Docker Fundamentals

Image Layers

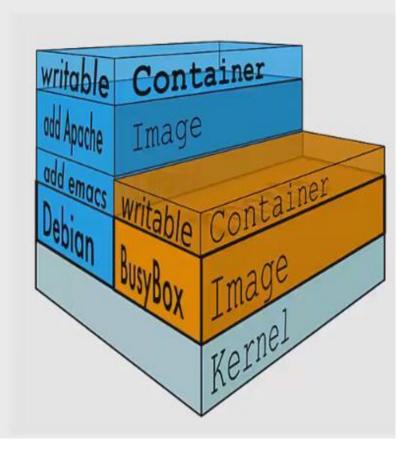

- Images are comprised of multiple layers
- A layer is also just another image
- Every image contains a base layer
- Docker uses a copy on write system
- Layers are read only

The Container Writable Layer

- Docker creates a top writable layer for containers
- Parent images are read only
- All changes are made at the writeable layer

Docker Commit

- docker commit command saves changes in a container as a new image
- Syntax docker commit [options] [container ID] [repository:tag]
- Repository name should be based on username/application
- Can reference the container with container name instead of ID

Save the container with ID of 984d25f537c5 as a new image in the repository username/application. Tag the image as 1.0 docker commit 984d25f537c5 username/application 1.0

User name

Application name

Build New Image

- EXERCISE
- 1. Create a container from an Ubuntu image and run a bash terminal docker run -i -t ubuntu:14.04 /bin/bash
- 2. Inside the container, install curl apt-get install curl
- Exit the container terminal
- 4. Run docker ps -a and take note of your container ID
- 5. Save the container as a new image. For the repository name use <your name>/curl. Tag the image as 1.0 docker commit <container ID> <yourname>/curl:1.0
- 6. Run docker images and verify that you can see your new image

Use New Image

- 1. Create a container using the new image you created in the previous exercise. Run /bin/bash as the process to get terminal access docker run -i -t <yourname>/curl:1.0 /bin/bash
- 2. Verify that curl is installed which curl

Intro to Dockerfile

A **Dockerfile** is a configuration file that contains instructions for building a Docker image

- Provides a more effective way to build images compared to using docker commit
- Easily fits into your continuous integration and deployment process

Dockerfile Instructions

- Instructions specify what to do when building the image
- FROM instruction specifies what the base image should be
- RUN instruction specifies a command to execute

```
#Example of a comment
FROM ubuntu:14.04
RUN apt-get install vim
RUN apt-get install curl
```

Run Instruction

- Each RUN instruction will execute the command on the top writable layer and perform a commit of the image
- Can aggregate multiple RUN instructions by using "&&"

```
RUN apt-get update && apt-get install -y \
curl \
vim \
openjdk-7-jdk
```

Docker Build

- Syntax docker build [options] [path] build context
- Common option to tag the build docker build -t [repository:tag] [path]

Build an image using the current folder as the context path. Put the image in the johnnytu/myimage repository and tag it as 1.0

docker build -t johnnytu/myimage:1.0 .

As above but use the myproject folder as the context path

docker build -t johnnytu/myimage:1.0 myproject

EXERCISE

Build from Dockerfile

- 1. In your home directory, create a folder called test
- In the test folder, create a file called "Dockerfile"
- 3. In the file, specify to use Ubuntu 14.04 as the base image FROM ubuntu:14.04
- 4. Write an instruction to install curl and vim after an apt-get update RUN apt-get update && apt-get install -y curl \ vim
- 5. Build an image from the Dockerfile. Give it the repository <yourname>/testimage and tag it as 1.0 docker build -t johnnytu/testimage:1.0.
- Create a container using your newly built image and verify that curl and vim are installed

CMD Instruction

- CMD defines a default command to execute when a container is created
- CMD performs no action during the image build
- Shell format and EXEC format
- Can only be specified once in a Dockerfile
- Can be overridden at run time

Shell format

CMD ping 127.0.0.1 -c 30

Exec format

CMD ["ping", "127.0.0.1", "-c", "30"]

Try CMD

- EXERCISE
- Go into the test folder and open your Dockerfile from the previous exercise
- 2. Add the following line to the end CMD ["ping", "127.0.0.1", "-c", "30"]
- 3. Build the image
 docker build -t <yourname>/testimage:1.1 .
- 4. Execute a container from the image and observe the output docker run <yourname>/testimage:1.1
- 5. Execute another container from the image and specify the echo command docker run <yourname>/testimage:1.1 echo "hello world"
- 6. Observe how the container argument overrides the CMD instruction

ENTRYPOINT Instruction

- Defines the command that will run when a container is executed
- Run time arguments and CMD instruction are passed as parameters to the ENTRYPOINT instruction
- Shell and EXEC form
- EXEC form preferred as shell form cannot accept arguments at run time
- Container essentially runs as an executable

```
ENTRYPOINT ["ping"]
```

Start and Stop Containers

- Find your containers first with docker ps and note the ID or name
- docker start and docker stop

List all containers

docker ps -a

Start a container using the container ID

docker start <container ID>

Stop a container using the container ID

docker stop <container ID>

Getting terminal access

- Use docker exec command to start another process within a container
- Execute /bin/bash to get a bash shell
- docker exec -i -t [container ID] /bin/bash
- Exiting from the terminal will not terminate the container

```
johnnytu@new-docker:~$ docker exec -it serene shockley bash
root@4cfbac7ba80a:/usr/local/tomcat# cd
root@4cfbac7ba80a:~# ps -ef
UID
          PID PPID
                                       TIME CMD
root
                                   00:00:03 /usr/bin/java
                0 3 04:57 ?
root
                                   00:00:00 bash
                   0 04:59 ?
     40 34 0 04:59 ?
                                   00:00:00 ps -ef
root
root@4cfbac7ba80a:~#
```

Deleting Containers

- Can only delete containers that have been stopped
- Use docker rm command
- Specify the container ID or name

Deleting local Images

- Use docker rmi command
- docker rmi [image ID]
 or
 docker rmi [repo:tag]
- If an image is tagged multiple times, remove each tag

Docker Hub Repositories

- Users can create their own repositories on Docker Hub
- Public and Private
- Push local images to a repository

Pushing Images to Docker Hub

- Use docker push command
- Syntax docker push [repo:tag]
- Local repo must have same name and tag as the Docker Hub repo

Push to Docker Hub

EXERCISE

- Login to your Docker Hub account
- Create a new public repository called "testexample"
- Tag your local image to give it the same repo name as the repository you created on Docker Hub

```
docker tag <yourname>/testimage:1.1
<yourname>/testexample:1.1
```

- 4. Push the new image to Docker Hub docker push <yourname>/testexample:1.1
- 5. Go to your Docker Hub repository and check for the tag

Volumes

A **Volume** is a designated directory in a container, which is designed to persist data, independent of the container's life cycle

- Volume changes are excluded when updating an image
- Persist when a container is deleted
- Can be mapped to a host folder
- Can be shared between containers

Mount a Volume

- Volumes are mounted when creating or executing a container
- Can be mapped to a host directory
- Volume paths specified must be absolute

Execute a new container and mount the folder /myvolume into its file system

docker run -d -P -v /myvolume nginx:1.7

Execute a new container and map the /data/src folder from the host into the /test/src folder in the container

docker run -i -t -v /data/src:/test/src nginx:1.7

Volumes in Dockerfile

- VOLUME instruction creates a mount point
- Can specify arguments JSON array or string
- Cannot map volumes to host directories
- Volumes are initialized when the container is executed

String example

VOLUME /myvol

String example with multiple volumes

VOLUME /www/websitel.com /www/website2.com

JSON example

VOLUME ["myvol", "myvol2"]

Uses of volumes

- De-couple the data that is stored from the container which created the data
- Good for sharing data between containers
 - Can setup a data containers which has a volume you mount in other containers
- Mounting folders from the host is good for testing purposes but generally not recommended for production use

Mapping ports

- Recall: containers have their own network and IP address
- Map exposed container ports to ports on the host machine
- Ports can be manually mapped or auto mapped
- Uses the -p and -P parameters in docker run

Maps port 80 on the container to 8080 on the host

docker run -d -p 8080:80 nginx:1.7

Automapping ports

- Use the -P option in docker run
- Automatically maps exposed ports in the container to a port number in the host
- Host port numbers used go from 49153 to 65535
- Only works for ports defined in the EXPOSE instruction

Auto map ports exposed by the NGINX container to a port value on the host

docker run -d -P nginx:1.7

EXPOSE instruction

- Configures which ports a container will listen on at runtime
- Ports still need to be mapped when container is executed

```
FROM ubuntu:14.04

RUN apt-get update

RUN apt-get install -y nginx

EXPOSE 80 443

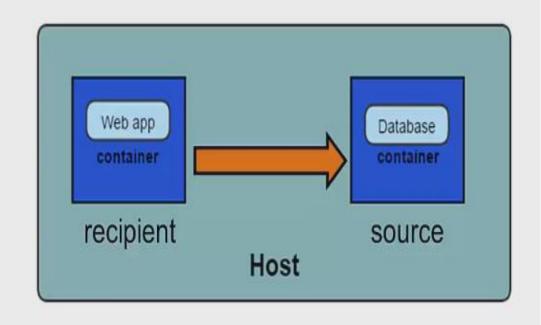

CMD ["nginx", "-g", "daemon off;"]
```

Linking Containers

Linking is a communication method between containers which allows them to securely transfer data from one to another

- Source and recipient containers
- Recipient containers have access to data on source containers
- Links are established based on container names

Creating a Link

- Create the source container first
- 2. Create the recipient container and use the --link option
- Best practice give your containers meaningful names

Create the source container using the postgres

docker run -d --name database postgres

Create the recipient container and link it

docker run -d -P --name website --link database:db nginx

Command Reference

- docker images
 https://docs.docker.com/reference/commandline/cli/
- docker ps https://docs.docker.com/reference/commandline/cli/#ps
- docker build https://docs.docker.com/reference/commandline/cli/#build
- docker tag <u>https://docs.docker.com/reference/commandline/cli/#tag</u>
